Abstract. A catalogue of 361 galactic contact binaries is presented. Listed contact binaries are divided into five groups according to the type and quality of the available observations and parameters. For all systems the ephemeris for the primary minimum, minimum and maximum visual brightness and equatorial coordinates are given. If available, photometric elements, $(m_1 + m_2) \sin^3 i$, spectral type, parallax and magnitude of the O'Connell effect are also given. Photometric data for several systems are augmented by new observations. The quality of the available data is assessed and systems requiring modern light-curve solutions are selected. Selected statistical properties of the collected data are discussed.

Key words: contact binaries – photometry – orbital period

1. Introduction

Eclipsing binaries of the W UMa type are systems with components sharing a common envelope located between the inner and outer critical surface in the Roche model. Most systems have components of the later spectral type (usually between F and K), nearly equal surface temperatures and mass ratios usually between $q = m_2/m_1 \approx 0.2 - 0.5$. Since the amplitude of the light curve (hereafter LC) decreases with decreasing mass ratio, the lower limit is unsure. The most extreme mass-ratio systems are difficult to detect. The present record holder is SX Crv $q = 0.066$ (Rucinski et al., 2001). Fortunately, the light of W UMa binaries varies continuously during the orbital cycle making the interval of the inclinations for which eclipses occur quite large (see Fig. 3 of Mochnacki & Doughty, 1972). Hence, the probability of their discovery is higher than in detached systems. The LCs of most contact systems can be successfully explained by the common-envelope model, first introduced by Lucy (1968). According to the gravity darkening law

$$T_{local} \propto g_{local}^\beta \quad (1)$$

the local temperature is proportional to the local gravity. Usually it is assumed $\beta \approx 0.08$ for radiative envelopes and $\beta \approx 0.25$ for convective envelopes.

Hence, the more massive component (having larger surface gravity) should have a slightly higher temperature. This is observed only for a minority of the systems (A type according to the Binnendijk, 1970 classification). The rest of the systems (W type) belongs to the opposite type (more massive component cooler). For total or nearly total eclipses, a system can be reliably classified from the width and the shape of the eclipse. For partial eclipses, the type of the system can be inferred from LC and radial-velocity measurements. For A-type systems the primary minima (deeper eclipses) correspond to the transit of the smaller component, for W-type systems the primary minimum is occultation. Although visual LCs of the W-type systems can be successfully solved by decoupling the temperatures of the components (e.g., in Wilson & Devinney, 1971 code) this approach is inadequate in the far ultraviolet (see Eaton et al., 1980). The most widely accepted explanation of the W-type syndrome was set forth by Mullan (1975), who introduced cool starspots on the primary component. This possibility is supported by phenomena connected with spot activity: increased H_{α} emission, fast rotational velocity, flare events from X-ray to radio as well as LC disturbances seen preferably in the W-type systems. Circumstellar matter can affect the form of the LC, too, at least in some systems.

Due to the fact that components of a contact binary are formed from almost normal, hydrogen-core-burning stars obeying mass-radius relation for main-sequence stars, the surface temperature of a contact binary depends on the orbital period. This, so called period-colour relation, first noticed by Eggen (1967) is an important tool for the contact-binary research. According to Wang (1994)

$$(B - V)_0 = 0.062 - 1.31 \log P, \quad (2)$$

where $(B - V)_0$ is the intrinsic colour index and P is the orbital period in days.

A separate group of the contact binaries is formed by hot stars of OB spectral types, where the common envelope is radiative (see Figueiredo et al., 1994). For a more detailed review and the status of the contact-binary research the reader is referred to the papers of Rucinski (1993), Maceroni & van't Veer (1996).

The number of eclipsing binaries displaying the W UMa-type LC (EW) is quickly increasing. While the 4th edition of the General Catalogue of the variable stars listed 561 objects as EW variables, its 4.1 electronic edition includes as many as 715 such variable stars. Most of them have only scant observations. Some of them are members of galactic clusters. The group of contact type binaries has mainly been extended by the OGLE experiment (Rucinski, 1997a, 1997b), ROTSE CCD survey (Akerlof et al., 2000), MISAO¹, the EINSTEIN X-ray survey (Fleming et al., 1989) and the Hipparcos mission (ESA, 1997). The Hipparcos satellite also provided LCs and minima times of many neglected southern contact systems (for 1991) as well as parallaxes used by Rucinski &

¹see <http://www.aerith.net/misao/index.html>

Duerbeck (1997) to derive the absolute magnitude calibration of contact binaries:

$$M_v^{\text{cal}} = -4.44 \log P + 3.02(B-V)_0 + 0.12, \quad (3)$$

where the orbital period P is in days.

The photometric data available for W UMa variables have recently been augmented by high-quality radial velocities obtained mainly at the David Dunlap Observatory (Lu & Rucinski, 1999, Rucinski & Lu, 1999, Lu et al., 2001, Rucinski et al., 2000, 2001, 2002). While the number of systems with reliable light and radial velocity solutions based on the Roche geometry was lower than 40 in 1996 (Maceroni & van't Veer, 1996) the present catalogue lists as many as 92 systems. The presence of the third light in the photometric LC solutions, apparent orbital period changes due to the light-time effect as well as the presence of additional spectral lines using high-dispersion spectroscopy (see Hendry & Mochnicki, 1998) have shown that many contact binaries are members of multiple systems.

Since the number of known contact binaries is quickly increasing the catalogue lists systems found up to March 01, 2002.

2. New observations

To extend available data, new observations were obtained for systems with no ground-based photometry available (DN Cam, FN Cam, OU Ser, EX Leo, FI Boo) and several neglected systems (EP And, EQ Tau, AH Aur, CW Cas, GW Cep, V714 Mon). Part of the data have already been published (Pribulla et al., 2001, 2002b, Pribulla & Vaňko, 2001, 2002, Vaňko & Pribulla, 2001, Vaňko et al., 2001). New minima observed since March 2001 were used to update the ephemerides of AB And, BX And, EP And, V402 Aur, DU Boo, DN Cam, GW Cep, VW Cep, SW Lac, AW UMa, EQ Tau, TX Cnc, V714 Mon, WZ Cep, V857 Her, YY CrB, AH Tau, V432 Per, RW Com, U Peg. The $UBVR$ photoelectric photometry was performed at the Stará Lesná (SL) and Skalnaté Pleso (SP) observatories of the Astronomical Institute of the Slovak Academy of Sciences (for details on instrumentation and reduction see Pribulla et al., 2001). Times of the minima were determined by the Kwee & van Woerden, sliding integrations, center of mass and parabola fitting methods using *min77* code (Komžík, 2001).

3. Sources and structure of the catalogue

The main source of the catalogue is the improved GCVS 4.1 electronic edition² and recent issues of IBVS (systems not included in GCVS 4 (Kholopov et al., 1985)). Another valuable source of systems and cross-identifications was

²<ftp://cdsweb.u-strasbg.fr/pub/cats/II/214A>

the SIMBAD astronomical database³. References to the catalogued objects were found using the ADS database⁴. The Hipparcos discoveries were taken from ASCII CD-ROMs (Volume 17) of the Hipparcos Catalogue (ESA, 1997).

In the first step, systems with EW LC were inspected. Part of the low-amplitude systems classified as the eclipsing binaries of the W UMa LC were found in the recent literature as the RR Lyrae or δ Scuti pulsating stars (e.g., EF Cnc, CI Com, V939 Cyg, V945 Oph, VW CVn etc.) opposite cases were also found (DN Aur, V802 Aql, IT Her, V842 Her etc.). The catalogue does not list members of galactic clusters displaying EW LC since these systems are quite faint and the classification is uncertain. Exceptions are EP Cep and ER Cep with LC solutions available. Systems included into our catalogue were also chosen from new variables detected during the Hipparcos mission and denoted as showing EB LC (ESA, 1997), since the β Lyrae classification was often inferred from one erroneous observation in either of the minima. The inclusion of several low-amplitude systems (e.g., CT Cet, V386 Pav, CP Hyi, HN UMa etc.) with periods and ($B - V$) colours typical for contact systems (for discussion see Duerbeck, 1997) is problematic.

An important clue as to nature of the contact binary is the colour index which for W UMa binaries (at odds with pulsating stars) varies only very weakly with the orbital phase. Reliable classification of some low-amplitude variable stars is impossible without spectroscopic observations.

The present version of the catalogue lists 361 objects. We included all systems with CCD or photoelectric LC available or/and reliable spectroscopic data (277 objects, groups 1-4). Other objects (group 5) are mainly Hipparcos discoveries (41 systems) and systems with good photographic LC or reliable ephemeris.

4. Description of the catalogue

The following subsections describe individual parameters included in the catalogue in column order.

4.1. Name of the object

In the first column of both right and left halves of Table 1, the **name** of the object in the GCVS notation is given. For recent discoveries we used the last, 76th namelist of the variable stars, published in July 2001 (Kazarovets et al., 2001). For variables without definite GCVS name we used the following designations: V1 Aqr = GSC 5178-1376 (hereafter "GSC" omitted), V1 Aql = 5728-92, V1 Ari = 628-290, V1 Aur = 3376-287, V1 Boo = 2016-830, V2 Boo = 2022-79, V3 Boo = 2020-736, V4 Boo = 2020-873, V1 Cam = 4344-123, V1 CVn = 2530-488, V1 CMi = 4832-400, V1 Com = 1991-1390, V2 Com = 1991-1633, V1 Cyg =

³<http://simbad.u-strasbg.fr>

⁴http://adsabs.harvard.edu/abstract_service.html

3547-216, V2 Cyg = 3921-1531, V3 Cyg = 3551-81, V4 Cyg = 3564-3059, V1 Her = 3073-837, V2 Her = 2604-1671, V3 Her = 3094-120, V4 Her = 3099-905, V5 Her = 3100-1616, V6 Her = 2625-1563, V1 Lib = 5582-545, V1 Lyr = 2636-1753, V2 Lyr = 3131-476, V3 Lyr = 2646-1938, V4 Lyr = 3123-1618, V1 Mon = 752-2349, V1 Peg = 1172-1452, V1 Psc = 1193-972, V2 Psc = 608-143, V1 Sge = 1621-2192 and V1 Sex = 4917-22. Two stars, not included in the GSC catalogue but denoted on the CCD frames of the original paper are V31 and V32 Cam.

An asterisk after the name of the object indicates a remark following the table.

4.2. Type of the eclipses and classification of the object

Column **Type** gives the classification of the system according to its LC characteristics and relative temperatures of the components.

The systems are classified according to the Binnendijk (1970) scheme: systems with the primary minimum being the transit are of the A type, systems with the primary minimum being the occultation are of the W type. Contact binaries with hot components of the *OB* spectral types are assigned as E type. Systems in which the components are in physical but not in thermal contact (represented by W Crv) are denoted by B (reminding β Lyrae LC).

The type of the eclipses is also given: P = Partial, T = total. For systems which do not clearly show the interval of the constant light during the eclipse of the smaller component, the type of the eclipse is inferred from the geometrical elements. The smallest orbital inclination for which the system is total is the function of the mass ratio and fill-out parameter. The presence of total eclipses in the system is important for the assessment of the quality of the geometric elements inferred from photometric observations. The mass ratio can be reliably determined only for totally eclipsing pairs (see Mochnacki & Doughty, 1972). Unfortunately, the presence of third light can affect the determination of the mass ratio in totally eclipsing systems (e.g., EF Dra, Pribulla et al., 2001).

For instance, entry WT means that the system is of the W subtype according to the Binnendijk's scheme and the eclipses are total.

4.3. Group - column **G**

In present catalogue the contact binary stars are divided into five groups depending on available data (column **G**): (1) systems with both spectroscopic and photometric orbits, (2) systems without reliable photometry but with spectroscopic orbit, (3) systems with photometric orbit, (4) systems with unsolved photoelectric or CCD LC, (5) systems without good CCD or photoelectric LC but with frequent observations of minima which allowed the determination of a reliable ephemeris. Most of the systems in the second subgroup are Hipparcos discoveries for which reliable spectroscopy has been performed at the DDO.

Table 1. Availability of the selected parameters for all five groups (G1 - G5) of systems. * means that the parameter is available for part of the systems

Parameter	G1	G2	G3	G4	G5
Type of the system (AWEB+PT)	+	*	*	*	-
Ephemeris	+	+	+	+	+
No. of available pe or CCD minima (n)	+	+	+	+	+
Photometric mass ratio q_{ph}	+	-	+	-	-
Fill-out f	+	-	+	-	-
Inclination i	+	-	+	-	-
Temperatures $T_{1,2}$	+	-	+	-	-
$\Delta M = V_{max}^{II} - V_{max}^I$	+	-	*	*	-
Spectroscopic mass ratio q_{sp}	+	+	-	-	-
$(m_1 + m_2) \sin^3 i$	+	+	-	-	-
Spectral type	+	+	*	*	-
$\alpha_{2000}, \delta_{2000}$	+	+	+	+	+
V_{max}, V_{min}	+	+	+	+	+

The photometric elements for most systems were determined assuming Roche geometry (for the discussion see Maceroni & Van't Veer, 1996). The photometric elements of some systems of the third subgroup are just preliminary solutions performed by authors of original papers using the code Binary Maker 2.0 of Bradstreet (1993).

Table 1 gives the review of the parameters available for the systems in these groups.

4.4. Ephemeris of the system - columns $\mathbf{JD}_0^{\text{hel}}$, Period, n, N1

The ephemeris for the primary minimum ($\mathbf{JD}_{\text{hel}}^0$ and \mathbf{P}) is given for all systems. The $\mathbf{JD}_{\text{hel}}^0$ was recomputed to correspond to the last photoelectric or CCD minimum available. The ephemerides of most systems from the first group were determined fitting the data in the last section of the (O-C) diagram which is approximately linear. For most systems the comprehensive lists of the minima were taken from Kreiner et al. (2001). The minima were weighted according to Kreiner et al. (2001): visual $w = 1$, photographic and photovisual $w = 3$, CCD $w = 5$, photoelectric $w = 10$. For the systems of the Group 5 (and some from groups 1 and 3) there were no recently available times of minima. Hence the ephemeris was taken from GCVS 4 or from other source. Ephemerides presented for group 2 are determined from original spectroscopic conjunctions and Hipparcos ephemerides.

n means the number of photoelectric and CCD minima available.

For objects with reasonably long interval of observations the type of the observed period change is also indicated. In some systems the changes are caused by the light-time effect (hereafter LITE) due to the presence of other component(s) in the system. Surface activity (and resulting variable asymmetry of the

minima) of several systems is another possible cause of observed period variations. Circumstellar matter, mass transfer or/and mass loss can also play an important role in many systems.

Ephemerides for several systems (UZ CMi, V731 Her, V873 Aql, BK Vul, V344 Lac, V700 Cyg etc.) given in GCVS4 were found to be spurious. The ephemerides of BI Vul, BP Vul, V400 Lyr, EK Com, IT Her, VZ Lib, FM Vel, V1193 Cyg, V732 Her, VY Cru, MS Her and V676 Aql are also problematic. Future observations are necessary to find the true orbital periods.

The catalogue also lists variable stars denoted as pulsating variables in the Hipparcos Catalogue but reclassified (according to the period-colour diagram) later by Duerbeck (1997). Since the original period is a half of the true period and JD_0 gives the instant of the maximum we recomputed ephemerides by adding half of the original period to the epoch of the maximum. However, there is still ambiguity which minimum is the primary. Space motions, parallaxes, and spectroscopic investigations are needed for a definite classification of these systems.

For all four groups of contact binaries note 1 (column head **N1**) regards observed orbital period change:

- v orbital period is variable,
- v! fast or complicated variation of the orbital period,
- 3b orbital period is modulated by the LITE,
- 3b? orbital period is probably modulated by the LITE,
- :
- :: uncertain or spurious period,
- :: very uncertain or unreliable period.

4.5. Photometric elements - columns **q_{ph}**, **f**, **i**, **T₁**, **T₂**, **ΔM**, **N2**

The photometric elements for the systems in groups 1 and 3 were taken from literature. The geometry of a contact binary is given only by the mass ratio **q_{ph}**, inclination **i** and fill-out factor **f**:

$$f = \frac{\Omega - \Omega_{inn}}{\Omega_{out} - \Omega_{inn}}, \quad (4)$$

where Ω_{inn} and Ω_{out} correspond to the inner and outer critical surface, respectively. Ω is the surface equipotential of the system. The mass ratios $q = m_2/m_1$ are always ≤ 1 since the more massive component (even if cooler) is denoted as the primary. Apart from the geometric elements the temperatures of the components **T₁** and **T₂** are also given. The code used for the determination of the photometric elements is indicated in the column **N2**.

The following abbreviations were used:

<i>WD</i>	various versions of the W&D program (see Wilson & Devinney, 1971),
<i>L2</i>	Light2 software (Hill & Rucinski, 1993),
<i>LT</i>	Light software (Hill, 1979),
<i>BM</i>	Binary Maker 2.0 (Bradstreet, 1993),
<i>W3</i>	WUMA3 code (Rucinski, 1976),
<i>WDp</i>	Adapted W&D code using the Price algorithm (see Barone et al., 1993), grid search or genetic algorithms
<i>WDr</i>	W&D code taking into account radiation pressure (see Drechsel et al., 1994)
<i>BS</i>	BINSYN code (see Vinkó et al., 1996) using the Price algorithm
<i>ME</i>	Maximum entropy mapping (see Hendry & Mochnacki, 2000)
<i>DJ</i>	Djurasević's (1992a, 1992b) code
<i>EL</i>	Wood's (1972) ellipsoidal model
<i>KO</i>	Kopal's (1982ab) Fourier analysis method

Most LCs were solved using the 1992 version of the W&D code, the 1995 version is not very widespread. There are also many "improved" versions of the W&D code e.g., using the Price Algorithm (Barone et al., 1993). The LIGHT2 code is made up of two programs WUMA3 and LIGHT (see Hill & Rucinski, 1993). All these codes are based on Roche geometry and its consequences (for details regarding LC fitting codes see Kallrath & Milone, 1999). The solution of the Wood (1972) ellipsoidal model was given for AZ Vir and HT Vir. For V829 Her the photometric elements were determined using a broadening function and a LC fitting method (Lu & Rucinski, 1999). Elements of UX Eri were determined by an adapted Russell-Merill method (Mauder, 1972). The LC of AM Leo was solved by the Roche model based program of Binnendijk (1977). For GSC 4344-123 the parameters were computed using the NIGHTFALL program (see also Covino et al., 2000).

An additional parameter "s" denotes objects where a simultaneous fit of the radial velocities and LCs has been performed; this includes cases where LCs were solved using the spectroscopic mass ratio q_{sp} .

The magnitude of the O'Connell effect (column head $\Delta\mathbf{M}$) was taken either from Maceroni & van't Veer (1996) or from original papers. For some systems the magnitude and sign of the O'Connell effect $\Delta M = V_{max}^{II} - V_{max}^I$ changes; the value usually refers to the highest observed asymmetry of the LC.

4.6. Spectroscopic data - columns q_{sp} , M^* , sp .

If available the present catalogue gives the spectroscopic mass ratio q_{sp} (always ≤ 1) and $(m_1 + m_2) \sin^3 i$ denoted in the catalogue as M^* . For S Ant, AK Her and TY Pup only the semi-amplitude of the radial-velocity variations of the primary component has been published (see Batten et al., 1989). The spectral type of the primary component is also given (column sp).

4.7. Other parameters - columns α_{2000} , δ_{2000} , π , σ_π , \mathbf{V}_{\max} , \mathbf{V}_{\min} , Ref., N3

Some parameters were taken from other catalogues. Equatorial coordinates (columns α_{2000} and δ_{2000}) were taken from the SIMBAD database⁵. Parallaxes π and their standard errors σ_π in milliarcseconds [mas] are given only for the systems observed by the Hipparcos satellite (ESA, 1997). The maximum \mathbf{V}_{\min} and minimum \mathbf{V}_{\min} visual magnitudes of most systems are taken from the GCVS 4.1 (electronic version).

The column denoted as **N3** gives additional information regarding the particular system:

- H* Hipparcos discovery,
- R* ROTSE discovery,
- mv* member of a visual pair (at least a triple system),
- ms* third or multiple components to the system found in the spectra,
- A* unsure equatorial coordinates of the system
(uncertainty larger than 0.1')

The last column **Ref.** gives the references of the object. Usually one reference regards photometry and one spectroscopy. The catalogue is available in electronic form at <http://www.ta3.sk/~pribulla/contact.html>

5. Discussion and conclusions

The catalogue contains information on field contact binary stars. It brings a view of the range and the completeness of the study of these systems. The catalogue can be helpful for investigators who are preparing various observing campaigns or studying the individual systems in more detail.

Some systems were classified as KE and defined in the GCVS as "contact systems of early (O-A) spectral types, both components being close in size to their inner surfaces". According to new observations and computations at least a few of them fill their Roche lobes. Therefore the present classification of contact binary stars could not be more topical.

361 contact binary stars were catalogued. The number of systems with both photometric and spectroscopic data available is 92 (Group 1). There are still 24 systems with reliable spectroscopic orbits but without photometric orbits (Group 2). For 71 systems definite or preliminary photometric orbits were computed (Group 3). CCD or photoelectric LCs were published for 90 systems (Group 4). The catalogue lists also 84 systems without good LCs having a sufficient number of minima to provide the ephemeris (Group 5).

The range of periods of catalogized systems is: 0.22068 days (CC Com) - 1.8855 days (V382 Cyg), the latter being a member of the early-type contact binaries (spectral type of the components O7). The statistics of the period changes can not be done for all systems due to the low number of minima. For 34 sys-

⁵<http://simbad.u-strasbg.fr>

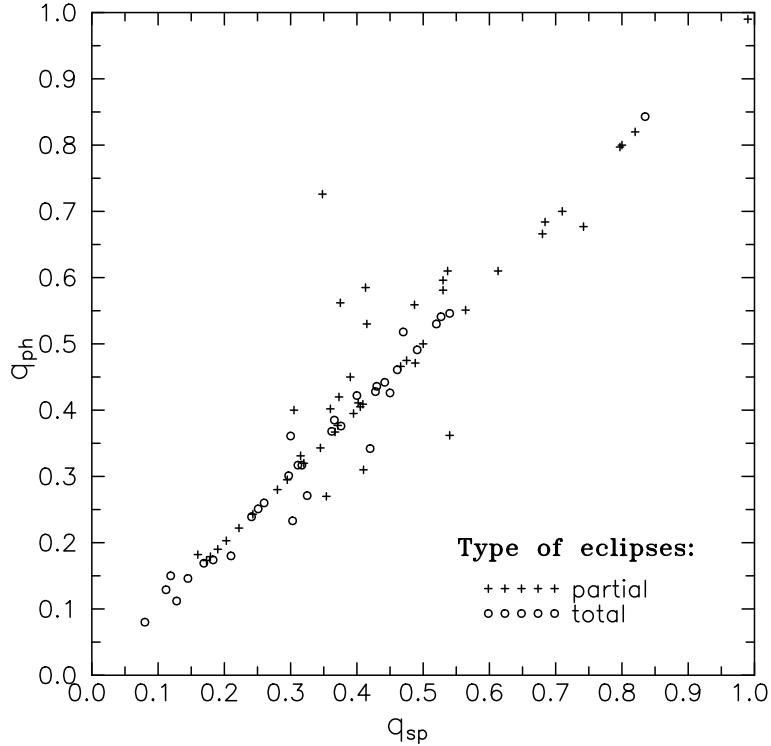

Figure 1. Spectroscopic versus photometric mass ratios for contact binaries in the first group with known type of eclipses (total/partial)

tems with more than 40 photoelectric and CCD times of minima the statistics are as follows: 8 systems show variable periods with alternating period increase and decrease, for 12 systems the orbital period increases and for 13 decreases and only in one case (BV Dra) it seems to be constant. The present mass ratio extremes for A-type systems are SX Crv ($q = 0.066$) and V753 Mon ($q = 0.97$) and for W-type systems KR Com ($q = 0.091$) and SW Lac ($q = 0.80$). There are several systems (CC Com, V523 Cas, AO Cam, AC Boo, LS Del, RZ Tau, XZ Leo, CK Boo, etc.) which show large differences between the photometric and spectroscopic mass ratio (see Fig. 1). This could be partly caused by the unreliability of photometric mass ratios for partially eclipsing systems, possibly third light reducing minima depths or low-quality photographic spectroscopy.

The maximum values of the fill-out parameter occur for early-type system CT Tau ($f = 0.98$) and for A-type systems TV Mus ($f = 0.87$), AW UMa ($f = 0.85$) and unreliably classified system AC Boo ($f = 0.91$). Unfortunately the fill-out parameter is tightly correlated with the gravity darkening coefficient and therefore cannot be reliably determined.

Table 2. Catalogue of the field binary stars

6. Remarks

AB And: Possible third body in the system with $P \approx 60$ years indicated in the (O-C) diagram.

BX And: The brighter component of the visual double ADS 1671. Separation $19.7''$. Possible presence of a third body on about a 60 year orbit seen in the (O-C) diagram.

SS Ari: Possible quadruple system. A third body is seen in the (O-C) diagram on an ≈ 44.8 years orbit. Possible fourth component on a 28 years orbit.

AP Aur: Fast period increase since the beginning of the observations (1901) with mean $\dot{P}/P = +2.12 \times 10^{-6} \text{year}^{-1}$. The (O-C) residuals deviate from the parabolic representation.

44i Boo: Fainter component of the visual double ADS 9494. The orbital period of the visual pair is 206 years.

TU Boo: Abrupt period decrease $\Delta P/P = -1.52 \times 10^{-5}$ around 1983.

TY Boo: Possible presence of a third body indicated by the sinusoidal variation ($P \approx 65$ years) seen in the (O-C) diagram.

TZ Boo: Two abrupt period changes around 1979 ($\Delta P/P = -2.45 \times 10^{-5}$) and around 1992 ($\Delta P/P = +3.27 \times 10^{-5}$).

VW Boo: Secular period decrease $\dot{P}/P = -4.97 \times 10^{-7} \text{year}^{-1}$ since the beginning of the observations (1938).

XY Boo: Fast period increase since the beginning of the observations (1944) with mean $\dot{P}/P = +1.56 \times 10^{-6} \text{year}^{-1}$. The (O-C) residuals deviate a lot from the parabolic representation.

AC Boo: Abrupt period increase $\Delta P/P = +2.32 \times 10^{-5}$ around 1980.

CK Boo: Abrupt period increase $\Delta P/P = +2.0 \times 10^{-5}$ around 1990.

V366 Cas: Period increase since the beginning of the observations (1911) with mean $\dot{P}/P = +5.27 \times 10^{-7} \text{year}^{-1}$. The (O-C) residuals deviate a lot from the parabolic representation.

V523 Cas: presence of the third body on ≈ 101 years seen in the (O-C) diagram.

VW Cep: The system is probably quadruple - $P_3 = 31.4$ years, $e_3 = 0.771$, $P_4 = 18.6$ years, $e_4 = 0.499$.

CV Cyg: Period decrease since the beginning of the observations (1898) with mean $\dot{P}/P = -4.43 \times 10^{-7} \text{year}^{-1}$ or two abrupt period decreases around 1930 and 1975.

V1073 Cyg: Period decrease with mean $\dot{P}/P = -4.88 \times 10^{-7} \text{year}^{-1}$ since the first photoelectric observation (1962). Old photographic observations give the impression of the sinusoidal period change.

EF Dra: Third component spectroscopically detected. Possible variation in the (O-C) diagram. Object discovered as an X-ray source.

UX Eri: Irregular period variation.

YY Eri: Sinusoidal variation seen in the (O-C) diagram interpreted as continuous mass transfer combined with LITE or cyclic magnetic activity. Abrupt period changes are another possibility.

AK Her: The brighter component of the visual double ADS10408. Separation $4.7''$. Quasi-sinusoidal period variation with two or more periodicities.

DF Hya: Period increase since the beginning of the observations (1935) with mean $\dot{P}/P = +4.24 \times 10^{-7} \text{year}^{-1}$ or abrupt period increase $\Delta P/P = +1.76 \times 10^{-5}$ around 1965.

EZ Hya: Fast period decrease since the beginning of the photoelectric observations (1969) with mean $\dot{P}/P = -1.46 \times 10^{-6} \text{year}^{-1}$. The (O-C) residuals deviate from the parabolic representation.

SW Lac: Presence of two other components in the systems seen in the (O-C) diagram with 23 and ≈ 90 years orbital periods. Multiplicity of the system confirmed by spectroscopic observations.

XY Leo: Multiple system. The third component on a $P \approx 20$ years orbit is a BY Dra binary with an orbital period 0.805 days.

AM Leo: The brighter component of the visual double ADS 8024. Separation $11.3''$. Possible presence of a third body indicated by the sinusoidal variation ($P \approx 33$ years) seen in the (O-C) diagram.

V502 Oph: A third body detected spectroscopically. A continuous decrease and a probable sinusoidal oscillation with a period of 35 yr in the (O-C) diagram.

V566 Oph: Abrupt period increase $\dot{P}/P = +1.41 \times 10^{-5}$ around 1972. Latest (O-C) residuals deviate from the linear representation.

V839 Oph: Orbital period seems to be modulated by more than one mechanism.

ER Ori: Member of a multiple system. The brighter component of IDS 05065-00840. Separation $13.6''$. Another component detected by speckle interferometry $0.19''$ distant. Complicated (O-C) diagram.

BX Peg: Period decrease since the beginning of the observations (1926) with mean $\dot{P}/P = -2.38 \times 10^{-7} \text{year}^{-1}$. Since 1986 period seems to be approximately constant.

AU Ser: Abrupt period decrease $\Delta P/P = -1.49 \times 10^{-5}$ around 1988.

RZ Tau: Variable period increase since the beginning of the observations (1916) with mean $\dot{P}/P = +2.37 \times 10^{-7} \text{year}^{-1}$.

AH Tau: Abrupt period decrease $\Delta P/P = -1.17 \times 10^{-5}$ around 1974. The (O-C) residuals before the change deviate from the linear representation.

EQ Tau: Possible third body ($P \approx 50$ years) indicated by the course of the (O-C) residuals.

W UMa: Complicated quasi-periodic change of the period since the beginning of the observations (1902).

TY UMa: Period increase since the beginning of the observations (1933) with mean $\dot{P}/P = +7.13 \times 10^{-7} \text{year}^{-1}$ or two abrupt period increases, the second around 1981.

AW UMa: Variation seen in the (O-C) diagram interpreted as LITE or two abrupt period decreases. The presence of a third body indicated by the systemic velocity changes.

AH Vir: The brighter component of a visual double ADS 8472 with ≈ 1280 years orbit. Presence of a third body on a 11.2 years orbit seen in the (O-C) diagram.

Acknowledgements. The authors would like to thank Dr. Chochol and the referee for valuable comments. This study was supported by VEGA grant 2/1157/21 of the Slovak Academy of Sciences and BS-033/M/2002 of Cracow Pedagogical University.
